

EXECUTIVE RISK ASSESSMENT

Digital Infrastructure Evaluation: Current Model vs Sonora Digital Token

This document evaluates structural digital risks present in the current operational model and contrasts them against a secure, containerized, role-segmented architecture (Sonora Digital Token / Mystic Core model). The analysis is oriented toward enterprise continuity, compliance, data governance, and executive-level operational control.

Dimension	Current Exposure	Proposed Architecture Impact
Credential Custody	Tax certificates (.cer/.key) stored in public cloud buckets. Passwords in plaintext files. No cryptographic control layer.	AES-256 encrypted storage. Backend-only access. Segregated credential vault. Full audit logging.
Operational Continuity	Single-point server dependency. Manual restart requirements. No containerized failover.	Dockerized microservices. Automatic restart policies. 24/7 monitored VPS deployment.
Access Governance	No strict RBAC (Role Based Access Control). High lateral movement risk.	Role-segmented dashboards (CEO, Finance, HR, Ops). Immutable activity logs.
Data Sovereignty	Critical financial files in third-party public cloud.	Encrypted with internal key management. Controlled API access. Optional offline encrypted backup.
Compliance Monitoring	Manual retrieval of tax compliance certificates. Reactive management model.	Scheduled automated validation. Real-time alerts for liabilities or anomalies.
Scalability	Operational processes tied to personnel.	Process-driven automation. Scalable container replication model.

Conclusion: The current system operates functionally but exposes the company to preventable digital identity, compliance, and continuity risks. The Sonora Digital Token architecture transitions the company from document-based management to infrastructure-based governance, reducing operational friction while increasing executive visibility and institutional resilience.
